A BETTER WAY TO SHARE SENSITIVE DOCUMENTS

Your documents.
Your consent.
Your control.

CNOSEND is a consent-first document sharing platform that gives people control over **why** a document is shared, **who** can access it, and **for how long**.

Purpose-bound Clear reason for every request	**Time-limited** Access expires automatically	**Revocable** Stop future access when needed

A privacy-first concept for everyday document workflows — from college admissions to healthcare and financial services.

THE PROBLEM → A CONTROLLED ALTERNATIVE

Document sharing needs more than an upload button.

Photocopies, email attachments and messaging apps make it easy to share documents — but hard to control what happens next.

TODAY’S GAP

- Documents are often shared without clear purpose or expiry
- Copies can be forwarded or retained beyond the original need
- Owners have limited visibility into access and reuse
- Consent is difficult to prove after the fact

THE CNOSEND APPROACH

- Requesters specify document type, purpose and duration
- Owners review the notice and explicitly approve or deny
- Access is checked against grant, expiry and revocation
- A tamper-evident consent trail supports accountability

Core principle: Share only what is needed, for the reason stated, for the time approved.

HOW IT WORKS

A simple consent flow, backed by verifiable records.

CNOSEND combines a private document layer with an on-chain record of consent events.

01	02	03	04	05
Create request	**Review terms**	**Grant or deny**	**Access securely**	**Revoke / expire**
Requester sets purpose, document type and duration.	Owner opens a QR code or secure link and reads the notice.	Owner explicitly approves or declines the request.	Server verifies permission, identity, expiry and status.	Owner can revoke; expiry blocks future access.

PRIVATE APPLICATION LAYER

Next.js + Supabase

Authentication, private document storage, access checks, consent dashboard and audit timeline.

MST BLOCKCHAIN LAYER

Solidity consent registry

Stores consent identifiers, terms hashes and event timestamps — not document files or personal information.

Important: Blockchain records provide tamper-evident evidence; they do not store documents or make screenshots impossible. Revocation blocks subsequent platform access, but cannot retract copies already made.
